

Power is directly drawn from the transformer distribution box

Overview

The power goes from the transformer to the distribution bus. Distribution substations connect to the transmission system and lower the transmission voltage to medium voltage ranging between 2 kV and 33 kV. From the transformer's low-voltage side (0. From there, it is routed to individual building distribution boxes (secondary distribution boxes), which subsequently supply power to unit-level distribution boxes. Primary distribution systems consist of feeders that deliver power from distribution substations to distribution transformers. Many feeders leave substation in a concrete ducts and are routed to a nearby pole. They operate at lower voltages than transmission lines and span cities, communities, and rural regions, establishing a complex network that assures power to every end user. Typical transmission voltages include 115 kV, 138 kV, 230 kV, 345 kV, 500 kV, and 765 kV.
